CT classifier accuracy on known, unknown and internet images

Share of images the deployed app labelled correctly, by where the images came from

- **Known dataset:** held-out test split of IQ-OTH/NCCD (Iraqi cancer centres), the only data the model was trained on
- **Unknown dataset:** normal slices from other hospitals (MosMedData, Rahimzadeh et al., via the Maftouni collection)
- **Internet images:** online “Chest CT-Scan images” collection (normal slices + three lung-cancer types)

Every image was sent through the live app with all checks on; images the app refused count as errors.

¹ Balanced accuracy = mean of the per-class accuracies for the classes in each set. Plain accuracy: known 98.1%, unknown 0.0%, internet 90.6% (inflated by the 261 cancer slices).

† Not evidence of skill: the app called all 318 CT slices from outside IQ-OTH/NCCD Malignant or Benign, including the 57 normal ones.
